Notes on the Indices of Agricultural Production

The attached tables present indices of agricultural production and food production for 12 countries of the Far East and 3 countries of South Asia. Sufficient information is not yet available to construct indices for Afghanistan and Nepal.

The base period used in preparation of these indices includes the three years, 1952 through 1954. Production of the various commodities is given in metric tons. To combine these commodities into one index it is necessary to utilize price weights. To determine these weights, farm prices (or prices as near the farm level as possible) per metric ton of the various agricultural commodities were collected for the 3 years of the base period from each country in which the commodity was produced. The individual commodity prices were averaged for the 3 years and expressed as a percent of the value of a metric ton of milled rice. These price relatives were weighted by average production in each country, and averaged for the entire region (both South Asia and the Far East). In some instances where price data were incomplete, judgment adjustments were made in the price weights. The price weight, therefore, represents the regional average farm value of a metric ton of each commodity relative to the value of a metric ton of milled rice. Thus, a metric ton of wheat, with a price weight of 85, is equal in value to .85 of a ton of milled rice.

To calculate agricultural production for each country, the production of each commodity was multiplied by the price weight and the resulting aggregates were summed. The total aggregate for a given year was then divided by the aggregate for the base period to obtain the index. The per capita indices were calculated by dividing the indices of total agricultural production by the population indices. Food production indices were calculated similarly, eliminating non-food items.

Indices were prepared for the years 1957, 1958, and 1959. Indices were also determined for the prewar period 1935-39.

Calendar year crop production is used for South Asia and the Far East. It includes crops harvested during the spring, summer, and autumn of 1959 (for example) and includes some crops, such as rice, the harvest of which starts in 1959 but continues into the early part of 1960. Data for livestock products are for the calendar year 1959.

Data for several minor crops which were not included in the indices in previous years are included this year. Some monor crops are still not included for some countries because of the lack of adequate data. Production estimates for several livestock products are also included in the indices, however, a separate index for livestock products was not calculated because of the minor importance of livestock in these regions, and the incompleteness and unreliability of information on livestock production.

Much of the data in this study is preliminary. All of it is based on the latest estimates of production furnished this office. It is acknowledged that the crop reporting procedures in many countries are inadequate and susceptible to error. The relationship of prewar production data to those of post-war merits special scrutiny. It is generally true, however, that whatever the shortcomings of the production figures, they are generally consistent from year to year so that the resulting indices can be regarded as reliable measures of the trend of production within a given country. Revisions of these computations will become necessary as better production data become available and as a critical study of existing data progresses.

The entire series of data for most of the countries were reviewed this year by the Agricultural Attaches. This has resulted in some important changes in the indices, particularly in the relationship between the pre-war and post-war period.
